

# **LC72131K** **LC72131KMA**

**ON Semiconductor®**

CMOS IC

## **PLL Frequency Synthesizer**

### **Overview**

The LC72131K and LC72131KMA are PLL frequency synthesizers for use in tuners in radio/cassette players. They allow high-performance AM/FM tuners to be implemented easily.

### **Features**

- High speed programmable dividers
  - FMIN: 10 to 160MHz ..... pulse swallower (built-in divide-by-two prescaler)
  - AMIN: 2 to 40MHz ..... pulse swallower
  - 0.5 to 10MHz ..... direct division
- IF counter
  - IFIN: 0.4 to 12MHz ..... AM/FM IF counter
- Reference frequencies
  - Twelve selectable frequencies (4.5 or 7.2MHz crystal)
  - 100, 50, 25, 15, 12.5, 6.25, 3.125, 10, 9, 5, 3, 1kHz
- Phase comparator
  - Dead zone control
  - Unlock detection circuit
  - Deadlock clear circuit
  - Built-in MOS transistor for forming an active low-pass filter
- I/O ports
  - Dedicated output ports: 4   • Input or output ports: 2   • Support clock time base output
- Serial data I/O
  - Support CCB format communication with the system controller.

Continued on next page.

• CCB is ON Semiconductor® 's original format. All addresses are managed by ON Semiconductor® for this format.

• CCB is a registered trademark of Semiconductor Components Industries, LLC.

# LC72131K, LC72131KMA

Continued from preceding page.

- Operating ranges
  - Supply voltage .....4.5 to 5.5V
  - Operating temperature ..... -40 to +85°C
- Packages
  - DIP22S(300mil) / MFP20J(300mil)

## Specifications

**Absolute Maximum Ratings** at  $T_a = 25^\circ\text{C}$ ,  $V_{SS} = 0\text{V}$

Parameter	Symbol	Pins	Conditions	Ratings	Unit
Supply voltage	$V_{DD}$ max	$V_{DD}$		-0.3 to +7.0	V
Maximum input voltage	$V_{IN1}$ max	CE, CL, DI, AIN		-0.3 to +7.0	V
	$V_{IN2}$ max	XIN, FMIN, AMIN, IFIN		-0.3 to $V_{DD}+0.3$	V
	$V_{IN3}$ max	$\overline{IO1}$ , $\overline{IO2}$		-0.3 to +15	V
Maximum output voltage	$V_{O1}$ max	DO		-0.3 to +7.0	V
	$V_{O2}$ max	XOUT, PD		-0.3 to $V_{DD}+0.3$	V
	$V_{O3}$ max	$\overline{BO1}$ to $\overline{BO4}$ , $\overline{IO1}$ , $\overline{IO2}$ , AOUT		-0.3 to +15	V
Maximum output current	$I_{O1}$ max	$\overline{BO1}$		0 to 3.0	mA
	$I_{O2}$ max	DO, AOUT		0 to 6.0	mA
	$I_{O3}$ max	$\overline{BO2}$ to $\overline{BO4}$ , $\overline{IO1}$ , $\overline{IO2}$		0 to 10	mA
Allowable power dissipation	$P_d$ max		$T_a \leq 85^\circ\text{C}$ [LC72131K]	350	mW
			$T_a \leq 85^\circ\text{C}$ [LC72131KMA]	180	mW
Operating temperature	$T_{opr}$			-40 to +85	°C
Storage temperature	$T_{stg}$			-55 to +125	°C

Note 1: Power pins  $V_{DD}$  and  $V_{SS}$ : Insert a capacitor with a capacitance of 2,000pF or higher between these pins when using the IC.

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

# LC72131K, LC72131KMA

**Allowable Operating Ranges** at  $T_a = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ ,  $V_{SS} = 0\text{V}$

Parameter	Symbol	Pins	Conditions	Ratings			unit
				min	typ	max

CE setup time	t <sub>ES</sub>	CE, CL	Note 2	0.75			μs
CE hold time	t <sub>EH</sub>	CE, CL	Note 2	0.75			μs
Data latch change time	t <sub>LC</sub>		Note 2			0.75	μs
Data output time	t <sub>DC</sub>	DO, CL	Differs depending on the value of the pull-up resistor. Note 2			0.35	μs
	t <sub>DH</sub>	DO, CE					

Note 1: Recommended crystal oscillator CI values:

$CI \leq 120\Omega$  (For a 4.5MHz crystal)

$CI \leq 70\Omega$  (For a 7.2MHz crystal)

The characteristics of the oscillation circuit depends on the printed circuit board, circuit constants, and other factors. Therefore we recommend consulting with the manufacturer of the crystal for evaluation and reliability.

Note 2: Refer to "Serial Data Timing".

## Pin Functions

Symbol	Pin No.		Type	Functions	Circuit configuration
	LC72131K	LC72131KMA			
XIN XOUT	1 22	1 20	X'tal OSC	Crystal resonator connection (4.5MHz/7.2MHz)	
FMIN	16	14	Local oscillator signal input	FMIN is selected when the serial data input DVS bit is set to 1. The input frequency range is from 10 to 160MHz. The input signal passes through the internal divide-by-two prescaler and is input to the swallow counter. The divisor can be in the range 272 to 65535. However, since the signal has passed through the divide-by-two prescaler, the actual divisor is twice the set value.	
AMIN	15	13	Local oscillator signal input	AMIN is selected when the serial data input DVS bit is set to 0. When the serial data input SNS bit is set to 1: <ul style="list-style-type: none"> <li>The input frequency range is 2 to 40MHz.</li> <li>The signal is directly input to the swallow counter.</li> <li>The divisor can be in the range 272 to 65535, and the divisor used will be the value set.</li> </ul> When the serial data input SNS bit is set to 0: <ul style="list-style-type: none"> <li>The input frequency range is 0.5 to 10MHz.</li> <li>The signal is directly input to a 12-bit programmable divider.</li> <li>The divisor can be in the range 4 to 4095, and the divisor used will be the value set.</li> </ul>	
CE	3	2	Chip enable	Set this pin high when inputting (DI) or outputting (DO) serial data.	
DI	4	3	Input data	Inputs serial data transferred from the controller to the LC72131K/KMA.	
CL	5	4	Clock	Used as the synchronization clock when inputting (DI) or outputting (DO) serial data.	
DO	6	5	Output data	Outputs serial data transferred from the LC72131K/KMA to the controller. The content of the output data is determined by the serial data DOC0 to DOC2.	
VDD	17	15	Power supply	The LC72131K/KMA power supply pin (VDD=4.5 to 5.5V) The power on reset circuit operates when power is first applied.	-
VSS	21	19	Ground	The LC72131K/KMA ground	-
$\overline{BO1}$ $\overline{BO2}$ $\overline{BO3}$ $\overline{BO4}$	7 8 9 10	6 7 8 9	Output port	Dedicated output pins The output states are determined by $\overline{BO1}$ to $\overline{BO4}$ bits in the serial data. Data: 0=open, 1=low A time base signal (8Hz) can be output from the $\overline{BO1}$ pin. (When the serial data TBC bit is set to 1.) Care is required when using the $\overline{BO1}$ pin, since it has a higher on impedance than the other output ports (pins $\overline{BO2}$ to $\overline{BO4}$ ).	
$\overline{IO1}$ $\overline{IO2}$	11 13	10 12	I/O port	I/O dual-use pins The direction (input or output) is determined by bits IOC1 and IOC2 in the serial data. Data: 0=input port, 1=output port When specified for use as input ports: The state of the input pin is transmitted to the controller over the DO pin. Input state: low=0 data value high=1 data value When specified for use as output ports: The output states are determined by the IO1 and IO2 bits in the serial data. Data: 0=open, 1=low These pins function as input pins following a power on reset.

Continued from preceding page.

Symbol	Pin No.		Type	Functions	Circuit configuration
	LC72131K	LC72131KMA			
PD	18	16	Charge pump output	PLL charge pump output When the frequency generated by dividing the local oscillator frequency by N is higher than the reference frequency, a high level is output from the PD pin. Similarly, when that frequency is lower, a low level is output. The PD pin goes to the high impedance state when the frequencies match.	
AIN AOUT	19 20	17 18	LPF amplifier transistors	The n-channel MOS transistor used for the PLL active low-pass filter.	
IFIN	12	11	IF counter	Accepts an input in the frequency range 0.4 to 12MHz. The input signal is directly transmitted to the IF counter. The result is output starting the MSB of the IF counter using the DO pin. Four measurement periods are supported: 4, 8, 32, and 64ms.

# LC72131K, LC72131KMA

## IF Counter Structure

The LC72131K/KMA IF counter is a 20-bit binary counter. The result, i.e., the counter's msb, can be read serially from the DO pin.

GT1	GT0	Measurement time	
		Measurement time (GT) (ms)	Wait time (twu) (ms)
0	0	4	3 to 4
0	1	8	3 to 4
1	0	32	7 to 8
1	1	64	7 to 8

The IF frequency ( $F_c$ ) is measured by determining how many pulses were input to an IF counter in a specified measurement period, GT.

$$F_c = \frac{C}{GT} \quad (C = F_c \times GT) \quad C: \text{Count value (number of pulses)}$$

## IF Counter Frequency Calculation Examples

- (1) When the measurement period (GT) is 32ms, the count (C) is 53980 hexadecimal (342400 decimal):  
IF frequency ( $F_c$ ) =  $342400 \div 32\text{ms} = 10.7\text{MHz}$

- (2) When the measurement period (GT) is 8ms, the count (C) is E10 hexadecimal (3600 decimal):  
IF frequency ( $F_c$ ) =  $3600 \div 8\text{ms} = 450\text{kHz}$

## IF Counter Operation

Before starting the IF count, the IF counter must be reset in advance by setting CTE in the serial data to 0. The IF count is started by changing the CTE bit in the serial data from 0 to 1. The serial data is latched by the LC72131K/KMA when the CE pin is dropped from high to low. The IF signal must be supplied to the IFIN pin in the period between the point the CE pin goes low and the end of the wait time at the latest. Next, the value of the IF counter at the end of the measurement period must be read out during the period that CTE is 1. This is because the IF counter is reset when CTE is set to 0.

Note: When operating the IF counter, the control microprocessor must first check the state of the IF-IC SD (station detect) signal and only after determining that the SD signal is present turn on IF buffer output and execute an IF count operation. Autosearch techniques that use only the IF counter are not recommended, since it is possible for IF buffer leakage output to cause incorrect stops at points where there is no station.

IFIN minimum input sensitivity standard		f [MHz]	
IFS	$0.4 \leq f < 0.5$	$0.5 \leq f < 8$	$8 \leq f \leq 12$
1: Normal mode	40mVrms (0.1 to 3mVrms)	40mVrms	40mVrms (1 to 10mVrms)
0: Degradation mode	70mVrms (10 to 15mVrms)	70mVrms	70mVrms (30 to 40mVrms)

Note: Values in parentheses are actual performance values presented as reference data.

## Unlock Detection Timing

### Unlock Detection Determination Timing

Unlocked state detection is performed in the reference frequency ( $f_{ref}$ ) period (interval). Therefore, in principle, unlock determination requires a time longer than the period of the reference frequency. However, immediately after changing the divisor N (frequency) unlock detection must be performed after waiting at least two periods of the reference frequency.

Figure 1 Unlocked State Detection Timing

For example, if  $f_{ref}$  is 1kHz, i.e., the period is 1ms, after changing the divisor N, the system must wait at least 2ms before checking for the unlocked state.

Figure 2 Circuit Structure

Figure 3

### Unlocked State Data Output Using Serial Data Output

In the LC72131K/KMA, once an unlocked state occurs, the unlocked state serial data (UL) will not be reset until a data input (or output) operation is performed. At the data output (1) point in Figure 3, although the VCO frequency has stabilized (locked), since no data output has been performed since the divisor N was changed the unlocked state data remains in the unlocked state. As a result, even though the frequency has stabilized (locked), the system remains (from the standpoint of the data) in the unlocked state.

Therefore, the unlocked state data acquired at data output (1), which occurs immediately after the divisor N was changed, should be treated as a dummy data output and ignored. The second data output (data output (2)) and following outputs are valid data.

### <Locked State Determination Flowchart Example>

## LC72131K, LC72131KMA

Directly Outputting Unlocked State Data from the DO Pin (Set by the DO pin control data)

Since the unlocked state (high=locked, low=unlocked) is output directly from the DO pin, the dummy data processing described in section 3 above is not required. After changing the divisor N, the locking state can be checked after waiting at least two reference frequency periods.

### Clock Time Base Usage Notes

The pull-up resistor used on the clock time base output pin ( $\overline{\text{BO1}}$ ) should be at least 100k $\Omega$ . This is to prevent degrading the VCO C/N characteristics when a loop filter is formed using the built-in low-pass filter transistor. Since the clock time base output pin and the low-pass filter have a common ground internal to the IC, it is necessary to minimize the time base output pin current fluctuations and to suppress their influence on the low-pass filter. Also, to prevent chattering we recommend using a Schmitt input at the controller (microprocessor) that receives this signal.

### Other Items

[1] Notes on the Phase Comparator Dead Zone

DZ1	DZ0	Dead zone mode	Charge pump	Dead zone
0	0	DZA	ON/ON	-0s
0	1	DZB	ON/ON	-0s
1	0	DZC	OFF/OFF	+0s
1	1	DZD	OFF/OFF	++0s

Since correction pulses are output from the charge pump even if the PLL is locked when the charge pump is in the ON/ON state, the loop can easily become unstable. This point requires special care when designing application circuits.

The following problems may occur in the ON/ON state.

- (1) Side band generation due to reference frequency leakage
- (2) Side band generation due to both the correction pulse envelope and low frequency leakage

Schemes in which a dead zone is present (OFF/OFF) have good loop stability, but have the problem that acquiring a high C/N ratio can be difficult. On the other hand, although it is easy to acquire a high C/N ratio with schemes in which there is no dead zone, it is difficult to achieve high loop stability. Therefore, it can be effective to select DZA or DZB, which have no dead zone, in applications which require an FM S/N ratio in excess of 90 to 100dB, or in which an increased AM stereo pilot margin is desired. On the other hand, we recommend selecting DZC or DZD, which provide a dead zone, for applications which do not require such a high FM signal-to-noise ratio and in which either AM stereo is not used or an adequate AM stereo pilot margin can be achieved.

# LC72131K, LC72131KMA

## Dead Zone

The phase comparator compares  $f_p$  to a reference frequency ( $f_r$ ) as shown in Figure 1. Although the characteristics of this circuit (see Figure 2) are such that the output voltage is proportional to the phase difference  $\phi$  (line A), a region (the dead zone) in which it is not possible to compare small phase differences occurs in actual ICs due to internal circuit delays and other factors (line B). A dead zone as small as possible is desirable for products that must provide a high S/N ratio.

However, since a larger dead zone makes this circuit easier to use, a larger dead zone is appropriate for popularly-priced products. This is because it is possible for RF signals to leak from the mixer to the VCO and modulate the VCO in popularly-priced products in the presence of strong RF inputs. When the dead zone is narrow, the circuit outputs correction pulses and this output can further modulate the VCO and generate beat frequencies with the RF signal.

Figure 1

Figure 2

### [2] Notes on the FMIN, AMIN, and IFIN Pins

Coupling capacitors must be placed as close as possible to their respective pin. A capacitance of about 100pF is desirable. In particular, if a capacitance of 1000pF or over is used for the IF pin, the time to reach the bias level will increase and incorrect counting may occur due to the relationship with the wait time.

### [3] Notes on IF Counting → SD must be used in conjunction with the IF counting time

When using IF counting, always implement IF counting by having the microprocessor determine the presence of the IF-IC SD (station detect) signal and turn on the IF counter buffer only if the SD signal is present. Schemes in which auto-searches are performed with only IF counting are not recommended, since they can cause false detection where there is no signal due to overflow from the IF counter buffer.

### [4] DO Pin Usage Techniques

In addition to data output mode times, the DO pin can also be used to check for IF counter count completion and for unlock detection output. Also, an input pin state can be output unchanged through the DO pin and input to the controller.
